#### Abstract

A set of 57 salicylanilides was synthesized, with the substitution being varied at positions $5,4^{\prime}$, and $3^{\prime}$. The substances were evaluated for antimycobacterial activity against the strains of Mycobacterium tuberculosis, Mycobacterium kansasii, and Mycobacterium avium. Structure-activity relationships were determined using the Free-Wilson method, which was further combined with the approach of Hansch. Antimycobacterial activity becomes higher with increasing electron-accepting ability of the substituents on the phenyl ring, and with increasing their lipophilicity. The influence of the substituents in position 5 is more complex.

The biological (antimicrobial, neuroleptic, analgetic, antiinflammatory, molluscoidean) activity, allergenic properties, and toxicity of salicylanilides were reviewed in the previous paper [1]. The photosynthesisinhibiting activity was found [2] as well. The mechanism of biological activity is not usually known. At present, mycobacterial infections caused by Mycobacterium avium constitute a serious problem. This type of infections endangers mainly birds, but it has been recently found that they are transferable to humans as well. These cases are somewhat rare, but they come, as a rule, to a fatal end. Following the results described in the review paper [1], we presume that it may be possible to modify the antimycobacterial effect of salicylanilides towards activity against $M$. avium. The results of studies on salicylanilides could also initiate further research of benzoxazine derivatives, as $2 H$-1,3-benzoxazin-2,4(3H)-diones are likely to have a similar pharmacophore [3, 4]. Thus, we decided to study the antimycobacterial activity of salicylanilides, in particular against the above strains which are potentially pathological. Antimycobacterial activity was assessed against the strains of Mycobacterium tuberculosis, Mycobacterium kansasii, and Mycobacterium avium. For the purposes of this study, we selected a series of salicylanilides substituted in position $5(\mathrm{H}$, $\mathrm{Br}, \mathrm{Cl}, \mathrm{F}, \mathrm{NO}_{2}$ ). The compounds were further modified by structural changes on the phenyl ring in the
anilide part of the molecule in order to achieve larger variations of electronic and hydrophobic parameters. The whole set consisted of 57 substances; nevertheless, a small number of them was not subjected to biological evaluation due to a limited solubility in water (no biological activity was detected within the range of their solubility).

The compounds are not commercially available, but a number of them have been described in the literature. We have reported the data on antimycobacterial activity of unsubstituted salicylanilides [5], which had been prepared before.

The results of biological assays were subjected to a QSAR analysis based upon a combination of the Free-Wilson and Hansch methods with modifications introduced in [6-8]. In our approach, the FreeWilson analysis is carried out first. From the obtained values expressing the influence of structural fragments on the biological activity, a relationship to physical and chemical molecular parameters is determined (e.g. to the substituent constants). The analysis is subsequently completed by attempting to find a correlation between biological activity and physicochemical data. For the salicylanilides described in this paper, the Free-Wilson analysis was carried out with regard to all kinds of biological activity which were observed, the values of the logarithms of partition coefficients (in octanol-water) were calculated using five differ-
ent ways, and their correlations to hydrophobic constants were studied. Following a careful consideration of significant structural parameters, attempts to find relationships between the substituent constants and the biological activity of salicylanilides were made.

## EXPERIMENTAL

The melting points were determined on a Kofler apparatus. The samples for analysis and antimycobacterial tests were dried over $\mathrm{P}_{4} \mathrm{O}_{10}$ at $61^{\circ} \mathrm{C}$ and 66 Pa for 24 h . Elemental analyses were performed on a CHNSO CE elemental analyzer (FISONS EA 1110, Milano). The IR spectra were measured in KBr pellets on a Nicolet Impact 400 apparatus; the absorption bands $\nu(\mathrm{C}=\mathrm{O})$ of salicylanilides were found in the region of $1612-1655 \mathrm{~cm}^{-1}$. The NMR spectra were recorded on a Varian Mercury-Vx BB 300 spectrometer operating at 300 MHz in deuteriochloroform. Chemical shifts were recorded as $\delta$ values and were indirectly referenced to tetramethylsilane via the solvent signal ( 7.26 for ${ }^{1} \mathrm{H}$ ). The ${ }^{1} \mathrm{H}$ NMR spectra are summarized in Table 2.

All regression equations were calculated with the use of the Multireg H program ( P . Klemera) for Microsoft Excel. The values of the Hammett constants $\sigma$ and hydrophobic substituent constants $\pi$ were taken from the literature [9] and are summarized in Table 4. The results of Free-Wilson calculations are given in Table 5. The logarithms of the partition coefficients were calculated using the CS ChemOffice program package, the PALLAS program, and the HyperChem package. The calculated partition coefficients are summarized in Table 6.

## Salicylanilides $\boldsymbol{I a}-\boldsymbol{V} \boldsymbol{l}$

All compounds were prepared by both methods.

## Method $A$

A solution of phosphorus trichloride ( 10 mmol ) in anhydrous pyridine ( $10 \mathrm{~cm}^{3}$ ) was added dropwise to a substituted aniline ( 20 mmol ) in anhydrous pyridine $\left(10 \mathrm{~cm}^{3}\right)$. After 30 min of stirring, a solution of salicylic acid ( 20 mmol ) in pyridine ( $10 \mathrm{~cm}^{3}$ ) was added to the mixture. After 3 h of heating, the reaction mixture was poured into $10 \%$ aqueous sodium carbonate ( $200 \mathrm{~cm}^{3}$ ), and the pH of the solution was adjusted to 8 . The resultant precipitate was filtered off, washed with water, and crystallized from ethanolwater (yields 50-80 \%).

## Method B

A suspension of substituted salicylic acid ( 0.02 mol ) and a substituted aniline ( 0.02 mol ) in chlorobenzene ( $100 \mathrm{~cm}^{3}$ ) was heated under reflux in the presence
of $\mathrm{PCl}_{3}(0.01 \mathrm{~mol})$ for 3 h . The reaction mixture was filtered while hot, and the product allowed to crystallize upon cooling, which yielded $80-95 \%$ of the theoretical amount. The product was recrystallized from ethanol-water (Table 1).

## Antimycobacterial Susceptibility Assay

For the evaluation of antimycobacterial activity of the substances in vitro, the following strains were used: M. tuberculosis CNCTC My 331/88, M. kansasii CNCTC My 235/80, M. avium CNCTC My $330 / 88$, obtained from the Czech National Collection of Type Cultures (CNCTC), National Institute of Public Health, Prague.

Antimycobacterial activity of the compounds against these strains was determined by the microdilution broth method, in the Sula semisynthetic medium (SEVAC, Prague).

The compounds were added to the medium in a dimethyl sulfoxide solution. The following numerical values of concentrations $\left(c /\left(\mu \mathrm{mol} \mathrm{dm}{ }^{-3}\right)\right)$ were used: $1000,500,250,125,62,31,16,8$, and 4 . (The concentration of DMSO in medium $10 \%$, basic suspension of strains was carried out according to a standard having a concentration of 1 mg of bacterial mass per $1 \mathrm{~cm}^{3}$.) The minimum inhibitory concentrations were determined after incubation at $37^{\circ} \mathrm{C}$ for 14 d and 21 d by visual control. MIC was the lowest concentration of an antimycobacterially active substance (see the above concentrations), at which the inhibition of the growth of mycobacteria occurred. The DMSO has no inhibitory effect on this condition. The results are given in Table 3.

## RESULTS AND DISCUSSION

All salicylanilides were prepared by the treatment of salicylic acid with the appropriate aniline derivatives in the presence of phosphorus trichloride in pyridine or chlorobenzene as a solvent. A strong absorption band in the region of $\tilde{\nu}=1600-$ $1655 \mathrm{~cm}^{-1}$ assignable to an aromatic amide vibration $\nu(\mathrm{C}=\mathrm{O})$ was apparent in their infrared spectra. As the structure of the compounds is rather simple, the known ones were identified by the melting points, while the newly prepared substances were characterized by ${ }^{1} \mathrm{H}$ NMR spectra and their purity was checked by elemental analysis. The compounds are shown in Table 1 and their ${ }^{1} \mathrm{H}$ NMR spectral data are given in Table 2.

First physical and chemical parameters of the compounds were evaluated. Five approaches were used to calculate the logarithms of the partition coefficients ( $\log P$, octanol-water); three different fragmentations were employed in the ChemOffice package (fragmentations according to Ghose and Crippen [10], Viswanadhan et al. [11], and Broto et al. [12]). The

remaining two approaches were based on the PALLAS program which uses fragmentation developed by Rekker [13] and HyperChem [14]. Values calculated by different ways could be mutually correlated ( $r=$ $0.970-0.998, s=0.03-0.12$ ), and further correlations were found with constants $\pi$, but not with constants $\pi^{-}$. In order to determine the influence of the substituents from the acyl part of the molecule, we carried out the separation of the calculated $\log P$ values according to the Fujita and Ban [15] modification of the Free-Wilson approach. Within the series of our compounds, both groups of separated data correlated
to both $\pi_{m}$ values and $\pi_{p}$ values (the correlation to $\pi_{p}$ was somewhat more significant).

In the group of salicylanilides, there are two functional groups, which can be considered as the probable active centres with regard to the mechanism of action, i.e. the amide function and the hydroxy group. Substituents $\mathrm{R}^{2}$ (in the anilide part of the molecule) can strongly modify the electronic structure of the anilide moiety, but their influence over the hydroxy group is weaker. On the other hand, substituents $R^{1}$ (in the acyl portion of the molecule) can effect electron density in both groups; the influence on the amide and

hydroxy functions will be proportional to the substituent constants $\sigma_{m}$ and $\sigma_{p}$, respectively. This assumption was used as the starting point for further work. It can be concluded that substituent constants $\pi$ ( $\pi_{p}$ are probably more suitable for the acyl part) and substituent constants $\sigma$ (both $\sigma_{m}$ and $\sigma_{p}$ for the acyl part) can be used for the correlation of physical data with the biological activity of the compounds.

Antimycobacterial activity of the compounds was monitored after 14 d and 21 d of incubation. The logarithms of minimum inhibitory concentrations (log MIC) for both incubation periods are summarized in

Table 3. As there is a correlation between the results of evaluation after 14 d and $21 \mathrm{~d}(r>0.93, s<0.16)$, only values obtained after a 14 -day period were further processed, which is more common. Given the described correlation, it can be presumed that the processing of values obtained after longer periods of time would yield similar results.

The correlations according to the general Hansch equation (correlation $\log \{$ MIC $\}$ with $\log P, \log \left(P^{2}\right)$ and Hammett constants, see Table 4) were not significant. We carried out the Fujita and Ban [15] modification of the Free-Wilson analysis (Table 5).

It is a disadvantage of the Free-Wilson analysis that predictions can be made only within the mosaic of the structural fragments which were used. In the second part of this work, we attempted to generalize our conclusions using our own method based on correlating the contributions of individual substructures with the substituent constants corresponding to physicochemical properties of the compounds under investigation (Table 6). Thus, following the above considerations, correlations with the substituent constants were set up. Eqns ( $1-3$ ) characterize the relationships between structure and antimycobacterial activity against M. tuberculosis, M. kansasii, and M. avium, respectively. In all the equations, index 1 denotes substituent constants from the acyl portion of the molecule, index 2 marks substituent constants from the anilide part. The remaining symbols are obvious and do not require explanation.

$$
\begin{gather*}

r=0.887 \quad s=0.199 \quad F=34.93 \quad n=53
\end{gather*}
$$

All the three equations show a similar dependence of antimycobacterial activity on the structural parameters for all strains of mycobacteria which were evaluated. The compounds become more efficient antimycobacterial agents with increasing electron-accepting influence of the substituents on the amide function,

and with the increase of their hydrophobicity. Another positive factor contributing to the activity is the electron-donating influence of the substituents on the
hydroxy group. This finding can be utilized in the design of further salicylanilides with antimycobacterial activity. It also demonstrates the importance of the
union between physical organic chemistry and bioorganic chemistry.

In conclusion, salicylanilides described in this paper are important broad-spectrum antimycobacterial compounds, and the results can be utilized for the design of further compounds with significant activity. Conceptually, this work is an introduction to the study of similar derivatives of benzoxazine.

Acknowledgements. The work was supported by the Grant Agency of the Czech Republic (Grant No. 203/99/0030), the Ministry of Education of the Czech Republic (Project No. VS97124 and No. MSM 11160001), the Higher Education Development Fund (Grant No. 1304/2000), and the Charles University (Project No. 234/2000/BCH). We also thank D. Karlicková (Department of Pharmaceutical Chemistry and Drug Analysis, Faculty of Pharmacy, Charles University) for performing elemental analyses, J. Żižková (Department of Inorganic and Organic Chemistry, Faculty of Pharmacy, Charles University) for recording the IR spectra and analysis of halogen content, B. Janícková and M. Maliková (National Reference Laboratory for Mycobacterium kansasii, Regional Institute of Hygiene, Ostrava) for their assistance in antimycobacterial assays.
